Supply Chain ML Website

Introduction:

The website version is intended to make the Supply Chain ML Predictor easier to use without requiring the user to run each notebook cell. The user enters shipment details in a form and receives a prediction from the trained model.

Things we will need before using the website:

- The trained model and preprocessing file, or a backend that loads them.
- The supply chain dataset if the website includes a dataset upload or training option.

Theory/Procedure:

1. Select or upload the dataset (if this option is provided)

If the website asks for a dataset, select the file expected by the project. Check that the file is a supported format and contains the required supply chain columns. Some website versions may use a model that has already been trained and may not ask for a dataset at all.

2. Enter shipment details

- Payment / Type
- Category and Customer Segment
- Market and Region
- Shipping Mode
- Scheduled shipping days
- Order total and Quantity

Use the values and ranges shown by the website. Do not enter text into a numeric field or leave a required field blank.

3. Submit the prediction

Click the website's prediction button (the notebook button is labelled **Predict Delay Risk & Duration**). Wait until the request finishes. Avoid clicking repeatedly while a prediction is already being processed.

4. Read the result

The result may show the estimated late-delivery risk, predicted delay duration, status, estimated transit or arrival information, and a recommendation. Only treat fields actually displayed by the deployed website as available outputs.

Things we will be careful about:

- Predictions are estimates based on historical data. They are not guaranteed delivery outcomes.
